

FEATURES

- Ultra low power consumption:
0.45mA/Ch (0~500Kbps, Supply voltage: 3.0~5.5V)
- High data rate: π 13xA: 600Mbps
 π 13xM: 10Mbps
 π 13xU: 150kbps
- High common-mode transient immunity: 45 kV/ μ s typical
- High robustness to radiated and conducted noise
- Low propagation delay:
4.4 ns maximum for 5 V operation
5.2 ns maximum for 3.3 V operation
- Isolation voltages:
 π 13xx4: AC 4000Vrms
 π 13xx6: AC 6000Vrms
- Safety and regulatory approvals (Pending)
UL recognition:
4000Vrms/6000Vrms for 1 minute per UL 1577
CSA Component Acceptance Notice 5A
VDE certificate of conformity
DIN V VDE V 0884-10 (VDE V 0884-10):2006-12
 $V_{IORM} = 565V$ peak/849V peak
CQC certification per GB4943.1-2011
- 3.0 V to 5.5 V level translation
- AEC-Q100 qualification
- Wide temperature range: -40°C to 125°C
- 16-lead, RoHS-compliant, (W)SOIC package
- Unused input pin should be connected to default

APPLICATIONS

- General-purpose multichannel isolation
- Industrial field bus isolation

GENERAL DESCRIPTION

The π 1xxx are 2PaiSemi digital isolators product family. By using matured standard semiconductor CMOS technology and innovative design, these isolation components provide outstanding performance characteristics superior to alternatives such as optocoupler devices and other integrated isolators. The maximum propagation delay is 3.6 ns with a pulse width distortion of less than 0.3 ns at 5.0V operation. Channel matching is tight at 0.4 ns maximum. The π 1xxx isolator data channels are independent and are available in a variety of configurations with a withstand voltage rating of 4.0 kV rms to 8.0 kV rms and the data rate from 150Kbps up to 600Mbps (see the Ordering Guide). The devices operate with the supply voltage on either side ranging from 3.0 V to

FUNCTIONAL BLOCK DIAGRAMS

Figure1. π 130/ π 131/ π 132 functional Block Diagram

5.5 V, providing compatibility with lower voltage systems as well as enabling voltage translation functionality across the isolation barrier.

The fail-safe state is available in which the outputs transition to a preset state when the input power supply is not applied.

Figure2. π 130 typical Application Circuit

SPECIFICATIONS

ELECTRICAL CHARACTERISTICS—5 V OPERATION

All typical specifications are at $T_A = 25^\circ\text{C}$, $V_{DD1} = V_{DD2} = 5\text{ V}$. Minimum/maximum specifications apply over the entire recommended operation range of $4.5\text{ V} \leq V_{DD1} \leq 5.5\text{ V}$, $4.5\text{ V} \leq V_{DD2} \leq 5.5\text{ V}$, and $-40^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, unless otherwise noted. Switching specifications are tested with $C_L = 15\text{ pF}$ and CMOS signal levels, unless otherwise noted. Supply currents are specified with 50% duty cycle signals and $C_L = 0\text{ pF}$.

ESD CAUTION**ESD (electrostatic discharge) sensitive device.**

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 9.

Parameter	Rating
Supply Voltages (V_{DD1} , V_{DD2})	-0.5 V to +7.0 V
Input Voltages (V_{IA} , V_{IB}) ¹	-0.5 V to $V_{DDI} + 0.5$ V
Output Voltages (V_{OA} , V_{OB}) ²	-0.5 V to $V_{DDO} + 0.5$ V

Side 1 Output Current (I_{O1})	-10 mA to +10 mA
Side 2 Output Current (I_{O2})	-10 mA to +10 mA
Common-Mode Transients ⁴	-150 kV/ μs to +150 kV/ μs
Storage Temperature (T_{ST}) Range	-65°C to +150°C
Ambient Operating Temperature (T_A) Range	-40°C to +125°C

Notes:

¹ V_{DDI} is the input side supply voltage.

² V_{DDO} is the output side supply voltage.

³ See Figure 3 for the maximum rated current values for various temperatures.

⁴ Common-mode transients refer to the common-mode transients across the insulation barrier. Common-mode transients exceeding the absolute maximum ratings may cause latch-up or permanent damage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

Notes:

¹ Maximum continuous working voltage refers to the continuous voltage magnitude imposed across the isolation barrier. See the Insulation Lifetime section for more details.

² Insulation lifetimes for the specified test condition is greater than 50 years.

Truth Tables**Table 11. π 130/ π 131/ π 132 Truth Table (Positive Logic)**

V _{ix} Input ¹	V _{DDI} State ¹	V _{DDO} State ¹	Default Low (N0), V _{Ox} Output ^{1,2}	Default High (N1), V _{Ox} Output ^{1,2}	Test Conditions/Comments
Low	Powered ³	Powered ³	Low	Low	Normal operation
High	Powered ³	Powered ³	High	High	Normal operation
Don't Care ⁵	Unpowered ⁴	Powered ³	Low	High	Fail-safe output
Don't Care ⁵	Powered ³	Unpowered ⁴	High Impedance	High Impedance	

Notes:

¹ V_{ix} and V_{Ox} refer to the input and output signals of a given channel (A, B or C). V_{DDI} and V_{DDO} refer to the supply voltages on the input and output sides of the given channel, respectively.

² N0 is the π 130xx0/ π 131xx0/ π 132xx0 models; N1 is the π 130xx1/ π 131xx1/ π 132xx1 models. See the Ordering Guide.

³ Powered = Power Up (V_{CC} \geq V_{DDxUV+}), Power Down (V_{CC} \geq V_{DDxUV-}).

⁴ Unpowered = Power Up (V_{CC} < V_{DDxUV+}), Power Down (V_{CC} < V_{DDxUV-}).

⁵ Input pins (V_{ix}) on the same side as an unpowered supply must be in a low state to avoid powering the device through its ESD protection circuitry.

APPLICATIONS INFORMATION

OVERVIEW

The $\pi 130/\pi 131/\pi 132$ transmit data across an isolation barrier by layers of silicon oxide isolation.

The $\pi 130/\pi 131/\pi 132$ have very low propagation delay and high speed. The input/output design techniques allow logic and supply voltages over a wide range from 3.0 V to 5.5 V, offering voltage translation of 3.3 V, and 5 V logic. The architecture is designed for high common-mode transient immunity and high immunity to electrical noise and magnetic interference.

See the Ordering Guide for the model numbers that have the fail-safe output state of low or the fail-safe output state of high.

PCB LAYOUT

The $\pi 130/\pi 131/\pi 132$ digital isolators require no external interface circuitry for the logic interfaces. Power supply bypassing is strongly recommended at the input and output supply pins (see Figure 7). Bypass capacitors are most conveniently connected between Pin 1 and Pin 8 for V_{DD1} and between Pin 9 and Pin 16 for V_{DD2} . The recommended bypass capacitor value is between 0.01 μF and 0.1 μF . The total lead length between both ends of the capacitor and the input power supply pin must not exceed 10 mm.

Figure 7. Recommended Printed Circuit Board Layout

In applications involving high common-mode transients, ensure that board coupling across the isolation barrier is minimized. Furthermore, design the board layout such that any coupling that does occur equally affects all pins on a given component side. Failure to ensure this can cause voltage differentials between pins exceeding the Absolute Maximum Ratings of the device, thereby leading to latch-up or permanent damage.

PROPAGATION DELAY RELATED PARAMETERS

Propagation delay is a parameter that describes the time it takes a logic signal to propagate through a component. The propagation delay to a Logic 0 output may differ from the propagation delay to a Logic 1 output.

Figure 8. Propagation Delay Parameters

Pulse width distortion is the maximum difference between these two propagation delay values and is an indication of how accurately the timing of the input signal is preserved.

Channel matching is the maximum amount the propagation delay differs between channels within a single $\pi 130/\pi 131/\pi 132$ component.

Propagation delay skew is the maximum amount the propagation delay differs between multiple $\pi 130/\pi 131/\pi 132$ components operating under the same conditions.

JITTER MEASUREMENT

Figure 9 shows the eye diagram for the $\pi 130/\pi 131/\pi 132$. The measurement was taken using an Keysight 81160A pulse pattern generator at 10 Mbps with pseudorandom bit sequences (PRBS) $2(n - 1)$, $n = 14$, for 5 V supplies. Jitter was measured with the Keysight DSOS104A oscilloscope, 1 GHz, 20 GS/s with the DPOJET jitter and eye diagram analysis tools. The result shows a typical measurement on the $\pi 130/\pi 131/\pi 132$ with 47 ps p-p jitter.

Figure 9. $\pi 130/\pi 131/\pi 132$ Eye Diagram

INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation as well as on the materials and material interfaces.

The two types of insulation degradation of primary interest are breakdown along surfaces exposed to the air and insulation wear out. Surface breakdown is the phenomenon of surface tracking and the primary determinant of surface creepage requirements in system level standards. Insulation wear out is the phenomenon where charge injection or displacement currents inside the insulation material cause long-term insulation degradation.

Surface Tracking

Surface tracking is addressed in electrical safety standards by setting a minimum surface creepage based on the working voltage, the environmental conditions, and the properties of the insulation material. Safety agencies perform characterization testing on the surface insulation of components that allows the components to be categorized in different material groups. Lower material group ratings are more resistant to surface tracking and, therefore, can provide adequate lifetime with smaller creepage. The minimum creepage for a given working voltage and material

group is in each system level standard and is based on the total rms voltage across the isolation, pollution degree, and material group. The material group and creepage for the $\pi 130/\pi 131/\pi 132$ isolators are presented in Table 5.

Insulation Wear Out

The lifetime of insulation caused by wear out is determined by its thickness, material properties, and the voltage stress applied. It is important to verify that the product lifetime is adequate at the application working voltage. The working voltage supported by an isolator for wear out may not be the same as the working voltage supported for tracking. It is the working voltage applicable to tracking that is specified in most standards.

Testing and modeling show that the primary driver of long term degradation is displacement current in the silicon oxide insulation causing incremental damage. The stress on the insulation can be broken down into broad categories, such as dc stress, which causes very little wear out because there is no displacement current, and an ac component time varying voltage stress, which causes wear out.

The ratings in certification documents are usually based on 60 Hz sinusoidal stress because this reflects isolation from line voltage. However, many practical applications have combinations of 60 Hz ac and dc across the barrier as shown in Equation 1. Because only the ac portion of the stress causes wear out, the equation can be rearranged to solve for the ac rms voltage, as is shown in Equation 2. For insulation wear out with the silicon oxide materials used in these products, the ac rms voltage determines the product lifetime.

$$V_{RMS} = \sqrt{V_{AC\ RMS}^2 + V_{DC}^2} \tag{1}$$

or

$$V_{AC\ RMS} = \sqrt{V_{RMS}^2 - V_{DC}^2} \tag{2}$$

where:

V_{RMS} is the total rms working voltage.

$V_{AC\ RMS}$ is the time varying portion of the working voltage.

V_{DC} is the dc offset of the working voltage.

Calculation and Use of Parameters Example

The following example frequently arises in power conversion applications. Assume that the line voltage on one side of the isolation is 240 V_{AC RMS} and a 400 V_{DC} bus voltage is present on the other side of the isolation barrier. The isolator material is polyimide. To establish the critical voltages in determining the

creepage, clearance, and lifetime of a device, see Figure 10 and the following equations.

Figure10. Critical Voltage Example

141
22-
015

The working voltage across the barrier from Equation 1 is

$$V_{RMS} = \sqrt{V_{AC\ RMS}^2 + V_{DC}^2}$$

$$V_{RMS} = \sqrt{240^2 + 400^2}$$

$$V_{RMS} = 466\ V$$

This is the working voltage used together with the material group and pollution degree when looking up the creepage required by a system standard.

To determine if the lifetime is adequate, obtain the time varying portion of the working voltage. To obtain the ac rms voltage, use Equation 2.

$$V_{AC\ RMS} = \sqrt{V_{RMS}^2 - V_{DC}^2}$$

$$V_{AC\ RMS} = \sqrt{466^2 - 400^2}$$

$$V_{AC\ RMS} = 240\ V\ rms$$

In this case, the ac rms voltage is simply the line voltage of 240 V rms. This calculation is more relevant when the waveform is not sinusoidal. The value is compared to the limits for working voltage in Table 10 for the expected lifetime, less than a 60 Hz sine wave, and it is well within the limit for a 50-year service life.

Note that the dc working voltage limit in Table 10 is set by the creepage of the package as specified in IEC 60664-1. This value can differ for specific system level standards.
